ABSTRACT

The Dow-Jones Industrial Average, Standard and Poor (500) Index, and Barron's Confidence Index were tested by various FORTRAN programs, and the results were graphed and printed from the Control Data 1604 tapes. Moving averages of differing periods, exponential smoothing using various smoothing constants and orders, and the Trendex model were used in the analysis. These techniques are discussed and analyzed. The representative programs, printouts and graphs are included to assist in determining whether to concentrate on investment in common stock or to deemphasize this portion of the portfolio and replace it in whole or in part with cash or bonds.

The patience of the personnel assigned to the Computer Facility, U. S. Naval Postgraduate School, was greatly appreciated. The direction and encouragement of Professors L. Darbyshire and D. G. Williams of the U. S. Naval Postgraduate School also contributed greatly to the pursuance of this analysis.

CHAPTER I

INTRODUCTION

The stock market tells a story that can be heard by those who take the time to listen. There are many techniques available to assist in interpreting this story. Some of these indicators will be discussed and analyzed.

No attempt has been made to determine what stock to buy. The value in this thesis is to assist in determining whether to concentrate on investment in common stock or to deemphasize the common stock portion of a portfolio and replace it in whole or in part with cash or bonds. The assumption made here is that the probability favors the continuation of the trend in a broad index that now exists. This may be due in part to the fact that most averages are composed of active, well-publicized and widely owned issues whose market action individually is "normal" in the technical sense. Another reason is that the process of averaging smooths out vagaries of component stocks, and the result thus more truly reflects the deep and relatively steady economic trends and tides. It is a fact that such averages as the Dow-Jones and Standard and Poor do propagate excellent trend lines on their charts. Admittedly investors cannot trade in the averages; actual commitments must be made in individual issues. However, even experienced traders know that it pays to heed the broad market trend.

Several computer programs, written by the author in FORTRAN and run on a Control Data 1604, are included in the appendices. One subroutine, "DRAW", which is available at the U. S. Naval Postgraduate School, was

used to obtain the graphs. A limitation imposed by this subroutine is that only 900 data points can be plotted, and the maximum abscissa is 9 inches. These graphs include moving averages, exponential smoothing and the Trendex time series technique.

CHAPTER II

MOVING AVERAGES

Obtaining moving averages from the Dow Jones Industrial Average is one of the most informative methods of analysis. The determination of the period involved is somewhat controversial. Several periods were analyzed to ascertain the difference in characteristics. A 13 week moving average (13MA) is plotted with the Dow Jones Industrial Average (DJI) superimposed over it in figure 1. The computer program and data are included in appendix A. The Dow Jones Industrial Average was used as of the close of business each Friday from 1 April 1960 through 26 March 1964. If the market was closed on Friday, the last day the market was open during that week was used.

A 200 day moving average (200), figure 2, is more commonly used. This analysis was computed from 14 October 1960 through 26 March 1964. A disadvantage of this system is that the first 199 days of data are lost in computing the average. It is desirable to use a slow-moving average line to obtain a more reliable chart. It should be noted that there were only 3 basic changes to the trend between 14 October 1960 and 26 March 1964. These are clearly identified in figure 2, when the Dow Jones Industrial average broke out on the upside on 16 December 1960, hesitated slightly, and broke out on the upside on 28 December 1960. It broke through on the downside on 30 March 1962 forecasting the crisis of that spring. The current bullish trend was depicted by an upward breakthrough on 20 November 1962. It is true that there were some false breakthroughs; such as 22 November 1963 when President Kennedy was

assassinated, but these are either explained by outside forces or are a signal using the rules listed below.

The 13 week moving average in figure 1 does not seem to permit an analysis as well as the 100 or 200 day moving averages. It provides a faster reaction to trend changes, but the large number of intersections make the analysis more difficult. Monthly moving averages of periods 3 and 6 were tested, but proved unsatisfactory since the line moved too rapidly for an effective analysis.

The following interpretations of figures 1 and 2 are recommended:

(1) If the average line flattens out following a previous decline, or is advancing, and the Index penetrates that average line on the upside, this comprises a major buying signal.

(2) If the Index falls below the moving average price line while the average line is still rising, this also is considered to be a buying opportunity.

(3) If the Index is above the line and is declining toward that line, fails to go through and starts to turn up again, this is a buying signal.

(4) If the Index falls too fast under the declining average line, it is entitled to an advance back toward the average line and a buying opportunity for this short-term technical rise is indicated.

(5) If the average line flattens out following a previous rise, or is declining, and the Index penetrates that line on the downside, this comprises a major selling signal.

(6) If the Index rises above the moving average price line while the average line is still falling, this also is considered to be a selling opportunity.

(7) If the Index is below the line and is advancing toward that line, fails to go through and starts to turn down again, this is a selling signal.

(8) If the Index advances too fast above the advancing average line, it is entitled to a reaction back toward the average line and a selling opportunity for this short-term technical reaction is indicated [8].

Another system which is sometimes used is illustrated in figure 3. The computer program with output data is shown in appendix B. This program can be used in conjunction with the rules recommended for figure 2. For bear market insurance a very simple procedure to remember is that a sell signal is effected when the Dow Jones Industrial Average falls below the lower of the two moving average lines 1 .

CHAPTER III

TRENDEX MODEL

The Trendex model first came to the attention of the author when it was described by E. S. C. Coppock in the 15 October 1962 issue of *Baron's*. This discussion was limited to the bull market era between 1950 and 1962. This period has been extended through April 1964 using the Dow Jones Industrial Average on the last market day of the month, figure 4. To determine the broader applicability of this model, the Standard and Poor composite of 500 stocks (STPR) was used commencing in January 1928. Figure 5 indicates that there is also a correlation in bear markets.

Figure 6 superimposes the Trendex curve (TNDX) from the 13 week moving average on figure 1. Appendix A contains the Trendex output. Little advantage is gained here except that two indicators are available on one graph from the same data. An attempt with a 200 day moving average with Trendex was of no value because it increased too slowly.

The computer programs for the Dow Jones Industrial Average and the Standard and Poor (500) are similar and are included in appendices C and D respectively.

Reasonable assumptions about the growing family of investors might include the following: the vast majority have no special training as investors; being human, they tend to procrastinate; new investors indulge their hopes, fears and imaginations; since few people are truly temperate, most investors become in turn unduly optimistic and unduly pessimistic, and are swept along with the crowd. In short, then, psychological or

FIG. 6

emotional factors play a great part in determining the actions of most investors. A way to record and evaluate the ever-increasing impact of emotion on market prices should be added to the investor's tool box.

Despite words of warning, emotional buying and selling will continue, thereby increasing the amplitude of market movements. These movements can be highly profitable to the investor who can appraise them properly, detect their acceleration and deceleration and act accordingly; contrary to the emotions of the crowd. The crowd liquidates holdings during a panicky decline and ignores basic economic facts. They overdo because they are motivated by emotion rather than by reason. The distortion created by impulsive buying and selling can be great. Emotional influences on the stock market gather momentum until they reach a climax. Excesses are usually followed by corrections.

Time and change are the basic elements in evaluating trends. The selection of proper time spans for a study of rate of change determines the effectiveness of the technique. The persistence of a trend for many months is more reliable than trends of short duration for the majority of investors.

The Trendex model is based on the monthly percentage change of an acceptable index. This is more meaningful than points of change. Since it gives a so-called buy signal when the risk is low just prior to the start of an important sustained advance (the second phase of a bull market), it is of no value to the in-and-out trader.

The value of the 10 month weighted moving average (column 18) is posted to the current date, figure 4, and is a simple curve which oscillates above and below a zero line. In statistical theory, if the

emotional factor were not present in stock market prices, there would be no widely oscillating curve - the line would be nearly horizontal. Its waves are, in effect, a picture of the emotional, or irregular pattern, since the trend and cyclical variations have been removed. Seasonal factors are not considered in this model.

According to Mr. Coppock [4], well timed buying is far more difficult for the non-professional investor than timely selling. He, therefore, prefers to think of the curve as a very long-term buying guide and suggests buying several strong good-quality stocks for the long term when the curve first turns upward from a position below the zero line.

Although not as accurate, the maximum points provide a reasonable correlation with downswings of the market. This indicator is purportedly to be used in the purchase of high grade stocks which are to be held for a long period. However, utilization of this indicator in conjunction with other technical devices expands its applicability to the market in general.

Several refinements to this technique suggest themselves, some of which have been tested here; the use of a very broad composite as the source of raw data, improved sensitivity through the use of weekly data, and the use of a monthly mean price instead of a closing price. It is the opinion of the author that there is value in using this model in the selection of individual stocks; provided the pattern of the prices used is compatible to the moving average introduced. A shorter term signal will be provided by a weighted moving average with a shorter period.

CHAPTER IV

DISPARITY INDEX

This program, appendix E, provides an interesting result. An expression commonly heard is that since the Dow Jones Industrial Average is composed of only 30 stocks; it, therefore, cannot provide a good indication of the market. An index that contains more stocks should be used. Figure 7 demonstrates that there is a very close parallel between the Dow-Jones Industrials (DJI) and the Standard and Poor (500) (STPR). The usual thumb-rule of Dow Jones/Standard and Poor ratio of 10:1 was used. The Standard and Poor times 10 is subtracted from the Dow-Jones and plotted (DSPX) in figure 7.

This also provides a quick measurement of the market movement. If Standard and Poor (500) was up .25 on the day and the Dow-Jones Industrial Average was off .50, then there is a bullish 3 point disparity in favor of the Dow. The next move of the Dow would probably be an advance. The Standard and Poor Index would have reflected the fact that on that particular day the general market was stronger than the Dow-Jones Industrial Average said it was. The Dow should have advanced by 2.50 to be commensurate with the general market. A 4 point advance in the Dow-Jones Industrial Average should be matched by at least a .40 gain in the Standard and Poor Index. Anything considerably below .40 would indicate the Dow-Jones advance was not typical of the general market. A decline would be expected to follow; but not necessarily immediately. However, if this situation persists, the vulnerability of the market would increase. In the case of such disparities, one of two things would be

X-SCALE = $3.08E+01$ UNITS/INCH
Y-SCALE = $1.08E+02$ UNITS/INCH
DUNHAM 237 DJI VS STANDARD AND POORS 500 VS

FIG. 7

expected to take place. Either the general market would come up to the Dow or the Dow would come down to the market price level. Past performance indicates a higher probability of the latter. Blue chip issues are the last to fall in a bear market.

This measurement of differential is also valuable as a major intermediate market indicator, especially when measuring the extent that the blue chip issues are running ahead of the general market late in a bull cycle. The Disparity Index quickly reflects the initial degree of general market deterioration paralleling a decline in the Advance-Decline Index. The Advance-Decline Index reflects general deterioration in a market that is losing strength, but the Disparity Index measures the degree of vulnerability and suggests how far the Dow-Jones Industrial average will go on the probable reaction. Figure 7 indicates that a "behind-the-market" status for the blue chips on a negative disparity is quite rare.

CHAPTER V

EXPONENTIAL SMOOTHING

Moving averages have many of the desirable characteristics of a practical method for smoothing out fluctuations. They have a stable response to changes, and the rate of response can be controlled by the selection of the number of periods included in the average. The most serious drawback is to keep track of past data, so that the moving totals can be adjusted, adding new information and dropping old. It is difficult to change the rate of response.

Exponential smoothing is a special kind of moving average that does not require keeping a long historical record and cuts down on data-processing time. The rate of response can be adjusted readily.

The formula for this system is simply to add to the old average a fraction of the difference between the new data and the old average. It is usually written as: new average = α (new data) + $(1-\alpha)$ old average; where α is a fraction. In the program, appendix F, the new average = old average + α (new data - old average) to reduce the computer time.

The smoothing constant, alpha, that gives the equivalent of an N-month moving average is $\frac{2}{N+1}$. The total fraction of the weight given to all the data more than N-months old is $(1-\alpha)^{N+1}$. To approximate a 200 day moving average, a smoothing constant .01 was used. The same rules regarding the evaluation of moving averages apply here.

First order exponential smoothing does not track a trend in the data, but an apparent trend can be computed to correct the calculated

average for its effect. This can be more readily accomplished by second order exponential smoothing. This is merely a repeat of the first order system. The second order average is equal to the first order average plus a fraction of the difference between the first and second order averages. Figure 8 shows the first order average (ONE) and second order average (TWO) superimposed on the Dow-Jones Industrial Average using a smoothing constant of .01. A comparison with figure 2 shows the equivalence of the first order exponential to the 200 day moving average.

An attempt to forecast the Dow-Jones Industrial Average one day in advance is shown in appendix G. Figures 9 and 10 show daily plots of the Dow-Jones Industrial Average (DJI), the first order exponential average (ONE), the second order exponential average (TWO), the expected Dow-Jones (used in a statistical sense) (EDJI), the forecast (FCST) and the differential between the forecast and the actual Dow (EROR), for the period 30 August 1960 through 31 March 1964. Figure 9 shows a smoothing constant, α , of .01 which did not produce desired results. In figure 10 the smoothing constant was increased to .30, and much better results were received.

This preliminary model can readily be changed to produce a forecast with a longer lead time and to provide an automatic change in the smoothing constant when the system gets out of control, i.e. when the Dow-Jones varies more than a pre-determined value from the forecast.

CHAPTER VI

BARRON'S CONFIDENCE INDEX

The Confidence Index has been quoted weekly in Barron's since 1932. It has not been considered a market forecaster until relatively recently when it was popularized by Joseph E. Granville. The author first became aware of its use from Mr. Granville's article in the 7 September 1959 issue of Barron's, when he wrote, "Whatever the Confidence Index does not foresee is not important."

As its name suggests, the Index attempts to measure investor confidence. Specifically, it represents the ratio between the average yield of Barron's 10 highest-grade corporate bonds and that of Dow-Jones' 40 bonds. The ratio is high when investors demonstrate confidence by buying lower grade liens, low when they take refuge in top-grade issues. Correlated with the movements of the stock market, the Index becomes a highly sensitive forecasting instrument; predicting the extent, as well as the timing, of price advances and declines.

Generally speaking, changes in the Confidence Index precede those of the stock market by two to four months. Repetitive bottoms or tops in the Index usually signal very important near-term lows or highs in the Dow-Jones Industrial Average. Major tops for the market are signaled when it makes a sharp weekly upswing to a new high and then retreats immediately the following week. The low in the Index following an unbroke series of declines is often more significant than subsequent lows made after intermittent rebounds. According to Mr. Granville, the setting up of the next timing zone for market vulnerability is measured by

adding two to four months to the date of the previous Index high, regardless of an upturn in the Index at some time after that date. The maximum point of vulnerability is closer to the 60 day lead than to the 120 day lead.

The 40 bonds that are grouped in the Dow-Jones average are composed of 10 high grade rails, 10 second grade rails, 10 public utilities, and 10 industrials. Barron's 10 high grade corporate bonds list is comprised of 4 rails, 3 utilities, 2 oils, and U. S. Steel 4½'s 1986. The rises in the Confidence Index on 15 March 1963 and 7 February 1964 were due in large part to changes in the structure of the Index (see appendix H). On 15 March 1963 Chicago, Milwaukee, St. Paul & Pacific, 4's, 1994, and St. Louis, San Francisco, 4's, 1997, were substituted for Delaware, Hudson, 4's, 1963, and New York Lackawana & Western, 4½'s, 1973, in the Dow-Jones second grade rails; and U. S. Steel, 4½'s, 1986, was substituted for Texas Corp., 3's, 1965, in Barron's 10 High Grade Bonds. The reason for these changes, according to a telephone conversation with Barron's in New York, was due to the inactivity of the previous issues. The expiration of Delaware, Hudson, 4's, 1963, of course, necessitated replacement.

Correlations without logic are seldom reliable. The logic behind the Confidence Index is that it is simply pointing out the direction the smart money is moving. When the Index is going up, it means that the important money is moving away from the safest bonds toward more speculative bonds. When it declines, it means that the smart money is gravitating toward the safer issues and away from risk.

Smart money is that money which flows into equities before a rise

in the market. Conversely, if the market declines, the smart money is that money that jumps out of stocks first. The rationale is to see what the smart money is doing in the bond market, and the investor will know in advance what this money will do in the equity market; either come in or get out.

Figure 11 is a graph of the weekly Confidence Index (CONF) and the Dow Jones Industrial Average (DJI) weekly closing from 10 June 1960 through 26 March 1964. Since the Confidence Index varies only slightly in relation to the Dow-Jones, figure 12 was designed which subtracted 75 from the Index and multiplied the result by 20. This adjustment of the Index does not affect its relative merit if the difference in scale of figure 12 is acknowledged. The Index was also introduced into the Trendex model (TRDX) in figure 12 to determine if this model could be used as a predictive medium. The results were inconclusive. The data are included in appendix I for possible future evaluation.

To emphasize the sensitiveness and accuracy of the Confidence Index in the broadest possible terms, the stock market has never continued to rise following a series of Index declines. In the positive sense, the market has always risen following a rising trend in the Index and has fallen following a declining trend. The lead time is generally two to four months.

CHAPTER VII

CONCLUSION

Investors are constantly on the look-out for reliable means of forecasting stock market movements, particularly ones that signal not only major trends, but also intermediate swings and week to week changes. Scores of these techniques have emerged over the years, but only five or six are widely used. None of these tools is infallible.

Much more sophisticated models are now available as dynamic programming techniques have been developed and computer memory has been enlarged. Com-Stat, a division of Spear & Staff, Inc., Babson Park, Massachusetts, had a model developed which weighs the significance of many fundamental and technical factors that affect the market place. It purportedly employs dynamic programming of price, volume, rate of change, diffusion, momentum, psychology, accumulation, distribution, etc. The most probable trend is forecast based on these changes. By their technique, they claim to have established a \$30,000 portfolio on 22 June 1962 composed of a maximum of 10 stocks each having approximately equal amounts of capital invested in it. On 16 August 1963, after 30 transactions (which included 8 short sales), the portfolio had increased to \$52,783 for a gain of 75.9% in 14 months. This is merely one example of what can be done with an understanding of the stock market, computer programming and dynamic statistical models.

A new book, Granville's "New Key to Stock Market Profits," was received too late to be evaluated. However, this system readily lends itself to computer analysis. In general, he is dealing in the on-balance

volume, which is the difference between the cumulative upside volume and the cumulative downside volume. This can be graphed against the Dow-Jones Average, and it will generally precede the price action. A more sophisticated approach is to analyze the volume of each of the 30 Dow-Jones stocks and determine the upside and downside breakouts. This differential can be used as an indicator in conjunction with the on-balance volume.

The more indicators you watch the better equipped you will be to escape the delusions which attack those who are uninformed. When many indicators say one thing, and the market is seemingly doing the opposite, trust the indicators. That many indicators can't be wrong, because that many people can't be right.

APPENDIX C

To set up the Trendex model enter the date in the first column. Column two is the value of the Index at the close of business of the corresponding month. Columns three and five are the values of the Index 14 months ago and 11 months ago respectively. Columns four and six are the percentage change in the Index over 14 month and 11 month periods. The total of columns four and six are entered in column 7. Column 18 is a 10 month weighted moving total of column 7. This is simplified by recording in column 8 the current combined percentage changes (column 7) by 10. Last month's combined change multiplied by 9 is recorded in column 8. The change before that is multiplied by 8 and entered in column 10, and so on. The sum of all 10 of these figures (columns 8 through 17) is divided by 10 to produce the 10 month weighted moving average (column 18).

A more precise notation for computing columns 9 through 17 is:
Let $x_{i,j}$ = the element of the matrix formed by columns 9 through 17,
where $i = 10, 11, 12, \dots, n$; n = the number of months of data used; and
 $j = 9, 10, 11, \dots, 17$. It follows that:

$$x_{i,j} = (x_{i,7} - x_{i-l,7})(10-l) \quad i-l > 0$$

$$x_{i,j} = 0 \quad i-l < 0$$

where $l = 1, 2, 3, \dots, 9$; the number of months before the current value. The first nine values of column 7, therefore, have been suppressed in the Trendex models.

APPENDIX G

An attempt was made to forecast the Dow-Jones Industrial Average one day in advance. The expected Dow-Jones Industrial Average, in a statistical sense, is equal to twice the first order exponential average less the second order exponential average:

$$E(DJI) = 2(Sg1) - Dbl$$

The trend is $\frac{\alpha}{1-\alpha}$ times the difference in the first and second order exponential averages:

$$TREND = \frac{\alpha}{1-\alpha} (Sg1 - Dbl)$$

The forecast is the algebraic sum of the expected DJI and the trend.

$$FCST = E(DJI) + TREND$$

The last column is the forecast from the previous data less the current Dow-Jones.

$$ERROR(I) = FCST(I-1) - DJI(I)$$

```
